**ABSTRACT**

Embodiments for preventing data loss and allowing selective access data include systems and methods that determine that a file has been created or received; determine a fingerprint of the file, wherein the fingerprint is a record of the file for comparison to the file at a later time; determine at least one permitted use related to the file, wherein the permitted uses comprises a permitted user and a permitted action; determine that the file is being accessed by a user; determine whether the user is a permitted user of the file based on an identity of the user; compare the file to the associated fingerprint of the file when the user is a permitted user; determine the action being taken by the user when the file matches the associated fingerprint; and permit the action to occur when the action is a permitted action of the file.

## SECURE DATA ACCESS

## CLAIM OF PRIORITY UNDER 35 U.S.C. §119

This non-provisional U.S. patent application claims priority to U.S. provisional patent application No. 61/980,132, entitled "SECURE DATA ACCESS" filed Apr. 16, 2014, assigned to the assignee hereof, and hereby expressly incorporated by reference herein.

## BACKGROUND

Typical data loss prevention processes tend to take an "all or nothing" approach. Either users are given full access to read, copy, and modify targeted data or the users are prevented from accessing the targeted data entirely. Although the systems running these processes may keep data logs, selective permission to access files is not permitted. As a result, creators or owners of files do not have control over the file once the file is shared or made public. Thus, there is a need for a system and method for providing selective access to files after the file is shared or made public.

## BRIEF SUMMARY

The following presents a simplified summary of one or more embodiments of the invention in order to provide a basic understanding of such embodiments. This summary is not an extensive overview of all contemplated embodiments, and is intended to neither identify key or critical elements of all embodiments, nor delineate the scope of any or all embodiments. Its sole purpose is to present some concepts of one or more embodiments in a simplified form as a prelude to the more detailed description that is presented later.

In some embodiments, the system is designed to provide selective access to files, containers, and/or program data. The selective access is established in advance and, in some cases, defines both permitted users and permitted actions. For example, a file may be created, go through a registration process whereby the file is evaluated, approved for access by specific individuals, and a limited set of actions by one or more of the individuals is defined. A fingerprint or record of the file may also be made when the file is created, received, or changed according to a permitted action. The fingerprint is compared to the file at a later time to confirm that the file being acted upon is the file that was pre-approved. In this manner, the system provides for a pro-active security system that defines access and actions for specific files in advance. The system is an improvement over prior art system in that the disclosed system prevents unauthorized sharing before it occurs rather than tracking unauthorized sharing after the fact.

In a first aspect, a system and method for providing secure data access is disclosed. In some embodiments, the system is configured to determine that a file has been created or received; determine a fingerprint of the file, wherein the fingerprint is a record of the file for comparison to the file at a later time; and determine at least one permitted use related to the file, wherein the permitted uses comprises a permitted user and a permitted action. The system then stores the fingerprint and the permitted use in association with the file. In some embodiments, the system is further configured to determine that the file is being accessed by a user; determine whether the user is a permitted user of the file based on an identity of the user; compare the file to the associated fingerprint of the file when the user is a permitted user;

determine the action being taken by the user when the file matches the associated fingerprint; and permit the action to occur when the action is a permitted action of the file. Computer program products and computer-implemented methods that perform the same or similar steps are also contemplated according to the disclosure herein.

In another aspect, a system and method for creating secure data container is provided. In some embodiments, the system and method are configured to receive a request to create a container, wherein the container is a file system comprising access parameters that define one or more permitted actions and one or more permitted users for the container; determine duration parameters for the container, wherein the duration parameter comprise a time duration during which the container may be accessed; determine a fingerprint of the container, the fingerprint being a record of the container for comparison to the container at a later time; generate the container with the access parameters, duration parameters, and fingerprint; monitor the container for compliance with the access parameters, duration parameters, and fingerprint; and apply a consequence when the container is not in compliance with the access parameters, duration parameters, or fingerprint.

In a further aspect, a system and method for providing secure access to programming data is provided. In some embodiments, the system and method are configured to receive task protocols and registration requests; determine an allowed list based on the protocols or requests, the list comprising registered data and codes needed to execute a task; allow a user to establish a connection to a device to execute the task on the device; identify data being transferred to and from the device; compare the data being transferred and the allowable list; and determine that at least some of the data being transferred is allowable.

Other aspects and features, as recited by the claims, will become apparent to those skilled in the art upon review of the following non-limited detailed description of the invention in conjunction with the accompanying figures.

## BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

The present embodiments are further described in the detailed description which follows in reference to the noted plurality of drawings by way of non-limiting examples of the present embodiments in which like reference numerals represent similar parts throughout the several views of the drawings and wherein:

FIGS. 1A and 1B are a flowchart illustrating a system and method for providing a secure access file system in accordance with the embodiments presented herein;

FIG. 2 provides a block diagram illustrating a data loss prevention system, a third party system, and a target device, in accordance with various embodiments;

FIG. 3 is a flowchart illustrating a system and method for creating a virtual container for use in a secure access file system in accordance with various embodiments;

FIG. 4 is a flowchart illustrating a system and method for using a virtual container with a secure access file system in accordance with various embodiments; and

FIG. 5 is a flowchart illustrating a system and method for securing programming data in accordance with various embodiments.

## DETAILED DESCRIPTION

The embodiments presented herein are directed to systems, methods, and computer program products for preventing data loss through selective data access.

The embodiments of the disclosure may be embodied as a system, method, or computer program product. Accordingly, aspects of the present disclosure may take the form of an entirely hardware embodiment, an entirely software embodiment (including firmware, resident software, micro-code, etc.) or an embodiment combining software and hardware aspects that may all generally be referred to herein as a “circuit,” “module” or “system.” Furthermore, aspects of the present embodiments of the disclosure may take the form of a computer program product embodied in one or more computer readable medium(s) having computer readable program code embodied thereon.

Any combination of one or more computer readable medium(s) may be utilized. The computer readable medium may be a computer readable signal medium or a computer readable storage medium. A computer readable storage medium may be, for example, but not limited to, an electronic, magnetic, optical, electromagnetic, infrared, or semiconductor system, apparatus, or device, or any suitable combination of the foregoing. More specific examples (a non-exhaustive list) of the computer readable storage medium would include the following: an electrical connection having one or more wires, a portable computer diskette, a hard disk, a random access memory (RAM), a read-only memory (ROM), an erasable programmable read-only memory (EPROM or Flash memory), an optical fiber, a portable compact disc read-only memory (CD-ROM), an optical storage device, a magnetic storage device, or any suitable combination of the foregoing. In the context of this document, a computer readable storage medium may be any tangible medium that can contain, or store a program for use by or in connection with an instruction execution system, apparatus, or device.

A computer readable signal medium may include a propagated data signal with computer readable program code embodied therein, for example, in baseband or as part of a carrier wave. Such a propagated signal may take any of a variety of forms, including, but not limited to, electromagnetic, optical, or any suitable combination thereof. A computer readable signal medium may be any computer readable medium that is not a computer readable storage medium and that can communicate, propagate, or transport a program for use by or in connection with an instruction execution system, apparatus, or device.

Program code embodied on a computer readable medium may be transmitted using any appropriate medium, including but not limited to wireless, wireline, optical fiber cable, RF, etc., or any suitable combination of the foregoing. Computer program code for carrying out operations for aspects of the present embodiments of the disclosure may be written in any combination of one or more programming languages, including an object oriented programming language such as Java, Smalltalk, C++ or the like and conventional procedural programming languages, such as the “C” programming language or similar programming languages. The program code may execute entirely on the user’s computer, partly on the user’s computer, as a stand-alone software package, partly on the user’s computer and partly on a remote computer or entirely on the remote computer or server. In the latter scenario, the remote computer may be connected to the user’s computer through any type of network, including a local area network (LAN) or a wide area network (WAN), or the connection may be made to an external computer (for example, through the Internet using an Internet Service Provider).

Aspects of the present embodiments of the disclosure are described below with reference to flowchart illustrations

and/or block diagrams of methods, apparatus (systems) and computer program products according to embodiments of the embodiments of the disclosure. It will be understood that each block of the flowchart illustrations and/or block diagrams, and combinations of blocks in the flowchart illustrations and/or block diagrams, can be implemented by computer program instructions. These computer program instructions may be provided to a processor of a general purpose computer, special purpose computer, or other programmable data processing apparatus to produce a machine, such that the instructions, which execute via the processor of the computer or other programmable data processing apparatus, create means for implementing the functions/acts specified in the flowchart and/or block diagram block or blocks.

These computer program instructions may also be stored in a computer readable medium that can direct a computer, other programmable data processing apparatus, or other devices to function in a particular manner, such that the instructions stored in the computer readable medium produce an article of manufacture including instructions which implement the function/act specified in the flowchart and/or block diagram block or blocks.

The computer program instructions may also be loaded onto a computer, other programmable data processing apparatus, or other devices to cause a series of operational steps to be performed on the computer, other programmable apparatus or other devices to produce a computer implemented process such that the instructions which execute on the computer or other programmable apparatus provide processes for implementing the functions/acts specified in the flowchart and/or block diagram block or blocks.

#### Secure Data Access

Referring now to the figures, in FIG. 1 a system and method of providing secure data access is provided in accordance with some embodiments of this disclosure. In some embodiments, the system and method are configured to determine that a file has been created or received; determine a fingerprint of the file, wherein the fingerprint is a record of the file for comparison to the file at a later time; and determine at least one permitted use related to the file, wherein the permitted uses comprises a permitted user and a permitted action. These actions occur pro-actively and define selective permissions for one or more users in contrast to the all-or-nothing approach of prior art systems. In an embodiment, the system stores the fingerprint and the permitted use in association with the file, such as locally or on a network. In some embodiments, the system determines that the file is being accessed by a user; determines whether the user is a permitted user of the file based on an identity of the user; compares the file to the associated fingerprint of the file when the user is a permitted user; and determines the action being taken by the user when the file matches the associated fingerprint. In this manner, the system confirms that the user is authorized, that the action is permitted, and that file being acted upon is the proper version. At this point, the system will permit the action to occur when the action is a permitted action of the file.

Turning now to block 102, the system determines that a file or file system has been created or received. As used herein, a file is a collection of data organized as part of a computer system. For example, a file may be a document, a spreadsheet, a presentation, a database, an audio or video file, a text file, a file specific to an application, or the like. One skilled in the art would understand that many different

5

types of files are possible and the examples disclosed herein are merely exemplary. The file typically has a single name or identifier under which the data may be accessed. A file system is a plurality of files or a virtual container under which a plurality of files is organized. While the word “file” may be used herein, the word “file” may be interchanged with the phrase “file system” throughout this disclosure.

In an embodiment, the file is created by a user, a program, an operating system, or the like. For example, a user may generate a report that is stored as a document. The user creates the file through use of a program. In another embodiment, the file is automatically generated as part of a program. For example, a computer program may create a log of activities on a computer. In still another embodiment, the file is a component of the operating system and or a program associated with the operating system. A printer driver may be an example of a file that is a component of an operating system. Files may be created when initiated generated and saved or may be created when a new version of the file is saved.

In some embodiments, the file is received from a user, an external source, or a server on a network. For example, a user may be working with a file and decide to enter the file into the system disclosed herein. The user may input the file, email the file, or otherwise indicate that the file is to be treated by the system disclosed herein. In some embodiments, the file is received from an external source. For example, a file may be sent to the financial institution via a USB drive or emailed to the institution. In some embodiments, the file is stored on a server connected to the system via a network, such as a wireless or wired network.

In an embodiment, the system receives the file when the file is indicated as entered into the system. Some files may be not managed via the system, i.e., the steps of the method are not performed on all files associated with the financial institution. The file may require a positive entry into the system in order for the steps to be performed on the file. In some embodiments, all files or all files of a specific type are automatically entered into the system and a user must opt out for the file to not be entered into the system. For example, for a small enough institution, all files created may be entered into the system. For a larger system, all files of a specific type, e.g., all generated document files, may be automatically entered into the system.

In block 104, the system determines a fingerprint of the file or file system. In some embodiments, the fingerprint is a record of the file or file system for comparison to the file or file system at a later time. The fingerprint is an electronic record that stores information on the structure, content, and/or communication channels associated with the file. For example, the fingerprint may be similar to a database schema, which is a mathematical description of a database that permits comparison of the database with other databases. In some embodiments, the fingerprint is a copy of the file, e.g., a copy of the document, at a certain point in time, e.g., when the fingerprint is made. In some embodiments, the copy is compared to the original to determine whether any changes have been made between the copy and the original. In some embodiments, the fingerprint is updated each time a permitted action is performed on the file.

In an embodiment, the comparison is carried out by a computing device processor. The comparison may evaluate any one of or all of the structure, the content, and the communication channels of the file. The structure of the file is the data structure comprising the file. For example, the number of columns or rows in a spreadsheet may be part of the structure of the spreadsheet. The content of the file is the

6

data input into the file. The information in cells of the spreadsheet or the words and figures in a document are the content of the file. The communication channels are the connections between the file and external elements. For example, if a spreadsheet is automatically updated via an input interface, the connection to the input interface may be a part of the comparison. In some embodiments, a checksum calculation is used to determine whether the fingerprint is identical to the file.

As will be discussed in greater detail later, the fingerprint is used at a later time to make a comparison to a file being accessed or used at the later time. The comparison permits the financial institution to ensure that the file being accessed is the file for which permission to access was granted. The fingerprint comparison prevents files from being shared outside the financial institution if the file has not been reviewed and approved for external share. Small changes to the file may result in the comparison identifying differences and preventing the file from being accessed or shared. As should be understood, the acceptable level of difference between the fingerprint and the file may be adjusted by a user to reduce the number of times a change in the file is identified.

In block 106, the system determines at least one permitted use related to the file or file system. In some embodiments, the permitted use includes a permitted action and a permitted user. The system disclosed herein differs from prior art systems in that the system is a permission-based system that approves actions and users in advance. In contrast, prior art systems conduct a forensic process that logs access but evaluates shares after the share has occurred. In the embodiments disclosed herein, the system determines a permitted use in advance so that the file may be accessed only by permitted users and the file may be used only via permitted actions.

As used herein, a permitted action is a use of the file that is permitted by the system. For example, writing data to the file may be a permitted action. Editing data on a file, deleting data on a file, copying a file, sharing a file, establishing connections between the file and external sources, moving the file, viewing the file, and the like are all examples of actions that may be permitted actions. It should be understood that other actions, e.g., playing an audio file, may be permitted actions and that the list disclosed herein is merely exemplary.

As used herein, a permitted user is a user that is permitted to perform a permitted action on the file. The permitted user may be an employee of the financial institution or an external employee. In an embodiment, the permitted user is identified by means of a username and password. In some embodiments, entry codes, hardware identifiers, or the like are used to identify the permitted user.

In an embodiment, a system administrator, developer, reviewer, compliance officer, or the like will evaluate a file and determine which actions are permitted actions and/or which users are permitted users. In an embodiment, the system provides a default list of actions for the file or based on the file type. In some embodiments, the system scans the file for keywords or data types, e.g., social security numbers, account numbers, or the like, and automatically assigns permitted actions and/or permitted users that may be changed by the user. In some embodiments, the system requires additional approval to specify a permitted user from outside the financial institution.

In block 108, the system stores the fingerprint and the permitted use in association with the file or file system. The fingerprint and the permitted use are stored in association

with the file or file system so that the fingerprint and the permitted use may be evaluated when the file is accessed or used. In some embodiments, this means that the fingerprint and the permitted use are stored locally with the file. In some embodiments, the fingerprint and the permitted use are stored on a network and accessed when the file is accessed or used. In this embodiment, the file may not be accessible if the network is not available and the fingerprint and the permitted use cannot be evaluated.

In block 110, the system determines that a memory store comprising the file or file system is being accessed by a user. As used herein, memory store may be a hardware or software embodiment of memory that stores the file. For example, the memory store may be a partition on a hard drive that stores the file. The user may be accessing a folder in a directory structure of a computer in order to access the file. In some embodiments, the memory store is a virtual container that has access protections, as will be discussed in greater detail in regard to FIGS. 3 and 4. In another example, the memory store is a hardware device such as a USB drive or the like.

A user may be a representative of the financial institution or an external party. In some embodiments, the system is used to ensure that external users are permitted to view or access only files that have been pre-approved and checked for version consistency prior to access. In some embodiments, the user is an automated or on-demand computer process. For example, an application may initiate program code that causes the computer to copy the file to a network location, e.g., a cloud server. The system disclosed herein may evaluate the application to determine whether the application is a “permitted user” (as well whether the copying is a permitted action and the fingerprint of the file matches).

In some embodiments, “accessing” means that some portion of the file is viewable by the user. For example, seeing the name of the file means that the file is being accessed. In this example, opening a folder or directory structure that includes the file is accessing the file. In some embodiments, “accessing” means that the user is attempting to open the file. For example, the user is opening the file to read the contents of a document. “Accessing” may also mean copying the file, editing the file, or the like. In some embodiments, the definition of “accessing” may be specified by a user when the permitted use is defined.

In an embodiment, the system determines that the user is accessing the file based on evaluation of the user’s actions via a computing device processor. The system may determine that calls to the system have been initiated and that a request to open the file, view the file, or the like has been made.

In block 112, the system determines when the user is a permitted user for at least one of the file or file systems on the memory store. In an embodiment, the system determines whether the user is a permitted user by identifying the user and comparing the identity of the user to a list of permitted users. In an embodiment, the list of permitted users is stored in association, e.g., locally or on a network, with the file.

In an embodiment, the system determines that the user is a permitted user by evaluating the identity of the user. The identity of the user may be determined from a user login, a passcode, or the like. The list of permitted users may be present in a database that is accessed by the system. In some embodiments, the permitted users are at least one user that has been granted at least one permitted action with respect to the file. In some embodiments, the system evaluates the

memory store to identify all files protected by the disclosed system and identify the permitted users for each of the files.

In decision block 114, the system determines whether the user is a permitted user. As discussed, the system may determine this based on evaluation of a permitted or allowed users list. In block 116, the system prevents access to the memory store if the user is not a permitted user for the file or file system. In some embodiments, preventing access means that the user is not able to open the memory store. In other embodiments, preventing access means that the user is able to open the memory store but not able to view the file for which the user is not a permitted user. In still further embodiments, the user is able to view the file in the memory store but not able to conduct an action on the file, e.g., open the file, copy the file, delete the file, or the like.

In block 118, the system compares the file or file system to the associated fingerprint of the file or file system when the user is a permitted user of the file. This step ensures that while the user may be a permitted user for the file, the system is also confirming that the file has not changed since the user became a permitted user. In an embodiment, the system compares the file that is being accessed with the fingerprint of the file that is stored in association with, e.g., locally or on a network, the file. As discussed, the system compares the file via a computing device processor. In some embodiments, a checksum is created to determine whether the file and the fingerprint are a match based on the structure, the content, and/or the communication channels associated with the file.

In decision block 120, the system determines whether the fingerprint is a match. A match may mean an identical match in all areas that the system is evaluating, e.g., structure, content, communication channels. In some embodiments, a text comparison is performed to identify changes such as updates, new versions, edits, or deletions to the content of the file. In some embodiments, specific portions of the files are excluded from the analysis. For example, portions or metadata related to files may be excluded if these portions typically change without changing content. For example, current date or time may be recorded in the metadata when a file is accessed but this data does not indicate that the file changed from the time the fingerprint was created. In some embodiments, the match is within a specific level of similarity, e.g., 100% similarity, 99% similarity, 95% similarity, or the like. Algorithms for comparing files and determining levels of similarity or difference may be used.

In block 122, the system prevents access to the file or file system when the fingerprint is not a match. If the file does not match the fingerprint within the specified level, e.g., 100%, 95%, and the like, the system prevents access to the file. The user may not be able to open the memory store comprising the file, view the file in the memory store, and/or open the file in the memory store.

In block 124, the system provides access to the files or file systems on the memory store for which the user is a permitted user and for which the associated fingerprint matches the file or file system. In some embodiments, the system also prevents access to the files or file systems on the memory store for which the user is not a permitted user or the associated fingerprint does not match the file or file system.

In block 126, the system determines an action is being taken by the permitted user related to the accessible file or file system. For example, the user may be attempting to open the file, write to the file, copy the file, move the file, delete the file, or the like. As discussed, there are many variations of actions taken because file types covered by this disclosure

differ. Updating a database or playing a music file may be permitted actions for specific types of files.

In some embodiments, the action is being taken when the user attempts to initiate the action via a command input into the computer system. For example, double clicking on a file may be a command to open the file. The user may activate additional software that will copy, delete, or scan the file, thereby taken action on the file. An automated script that accesses a file is also taking action on the file. The determination of when an action is being taken may be dependent upon the type of file, as well.

In decision block 128, the system determines whether the action is a permitted action. In an embodiment, the system compares the action being taken to a list of permitted actions associated with the file. For example, the system may store a list of permitted action by permitted user for each file in a database that is accessed by the system when an action is being taken on a file protected by the system. In block 130, the system prevents the action when the action is not a permitted action. In an embodiment, an error message is displayed indicating why the action is prevented from occurring.

In block 132, the system permits the user to perform the action on the file or file system when the action is a permitted action. In an embodiment, the system does not prevent whatever action is being taken from being completed. For example, another program may open the file. Edits to the file may be saved. The file may be deleted, or the like. Based on this process, if an action is permitted then the user has permission to access the file, the file matches the fingerprint of the file stored in association with the file, and the action being taken is a permitted action for the file (and in some embodiments based on the user). In an embodiment, the system automatically updates the fingerprint when a permitted action is performed on a file.

In block 134, the system tracks the actions performed by the permitted user. In an embodiment, the system not only provides a front end selective permission system but also tracks actions performed or attempted by users. For example, the system may track all of the actions performed by permitted users and/or track the actions that are prevented either because the user is not a permitted user, the fingerprint does not match, or the action is not a permitted action. In some embodiments, the system also tracks the data passing out of the secure file or secure container.

In some embodiments, the system and method are used to provide secure data access. For example, the system may be used to provide protection to files or file systems whereby the file is prevented from unauthorized sharing or other actions. The system also confirms that the file that is being shared is the file that approval was provided for. In this way, the system ensures that the action taken is permitted and the file being acted upon is the proper version for sharing. The system and method improves upon the forensic nature of prior art methods, which may track sharing but only identify problems with sharing after the fact. It should be understood that additional steps in the process may be performed while complying with the disclosure herein.

#### Environment for Providing Secure Data Access

Referring now to FIG. 2, a block diagram illustrates an environment 200 for providing secure data access. The environment 200 includes a target device 144, a data loss prevention system 142, and a third party system or device 152. The user 140 is associated with the target device 144 and can include an owner of the device 144, parties that have

authorized access to the device 144, an employee, associate, and the like. The target device 144 can include any type of device such as an ATM, a computing device, a mobile device, and so forth. The third party system 152 can include a system associated with a developer, technical support team, or a vendor. The environment 200 further includes one or more other third party systems 292 (e.g., a partner, agent, or contractor associated with the data loss prevention system 142), one or more other data loss prevention systems 294, and one or more external devices 296 (e.g., USB flash drives, hard drives, and other removable media). The systems and devices communicate with one another over the network 150 and perform one or more of the various steps and/or methods according to embodiments of the disclosure discussed herein.

The network 150 may include a local area network (LAN), a wide area network (WAN), and/or a global area network (GAN). The network 150 may provide for wireline, wireless, or a combination of wireline and wireless communication between devices in the network. In one embodiment, the network 150 includes the Internet.

The target device 144, the third party system 152, and the data loss prevention system 142 each includes a computer system, server, multiple computer systems and/or servers or the like. The data loss prevention system 142, in the embodiments shown has a communication device 242 communicably coupled with a processing device 244, which is also communicably coupled with a memory device 246. The processing device 244 is configured to control the communication device 242 such that the data loss prevention system 142 communicates across the network 150 with one or more other systems. The processing device 244 is also configured to access the memory device 246 in order to read the computer readable instructions 248, which in some embodiments includes registration applications 250 and data tracking applications 252. The data registration application 250 may be configured to approve a file or container identified in the target device 144 and generate a fingerprint for the file or container. The data tracking application 252 may monitor access and actions to files and containers associated with the target device 144. The memory device 246 also includes a datastore 254 or database for storing pieces of data that can be accessed by the processing device 244, such as permitted users or permitted actions associated with files or containers.

As used herein, a “processing device,” generally refers to a device or combination of devices having circuitry used for implementing the communication and/or logic functions of a particular system. For example, a processing device may include a digital signal processor device, a microprocessor device, and various analog-to-digital converters, digital-to-analog converters, and other support circuits and/or combinations of the foregoing. Control and signal processing functions of the system are allocated between these processing devices according to their respective capabilities. The processing device 214, 244, or 264 may further include functionality to operate one or more software programs based on computer-executable program code thereof, which may be stored in a memory. As the phrase is used herein, a processing device 214, 244, or 264 may be “configured to” perform a certain function in a variety of ways, including, for example, by having one or more general-purpose circuits perform the function by executing particular computer-executable program code embodied in computer-readable medium, and/or by having one or more application-specific circuits perform the function.

As used herein, a “memory device” generally refers to a device or combination of devices that store one or more

11

forms of computer-readable media and/or computer-executable program code/instructions. Computer-readable media is defined in greater detail below. For example, in one embodiment, the memory device 246 includes any computer memory that provides an actual or virtual space to temporarily or permanently store data and/or commands provided to the processing device 244 when it carries out its functions described herein.

The target device 144 includes a communication device 212 and communicably coupled with a processing device 214, which is also communicably coupled with a memory device 216. The processing device 214 is configured to control the communication device 212 such that the target device 144 communicates across the network 150 with one or more other systems. The processing device 214 is also configured to access the memory device 216 in order to read the computer readable instructions 218, which in some embodiments includes a data application 220 for running specific programs. The memory device 216 also includes a datastore 222 or database for storing pieces of data that can be accessed by the processing device 214.

The third party system 152 includes a communication device 262 communicably coupled with a processing device 264, which is also communicably coupled with a memory device 266. The processing device 264 is configured to control the communication device 262 such that the third party system 152 communicates across the network 150 with one or more other systems. The processing device 264 is also configured to access the memory device 266 in order to read the computer readable instructions 268, which in some embodiments include task applications 270 for performing various tasks such as debugging, troubleshooting, and so forth. The memory device 266 also includes a datastore 271 or database for storing pieces of data that can be accessed by the processing device 264.

In some embodiments, the data application 220 and the task applications 270 interact with the registration applications 250 and the data tracking applications 252 to receive and process registration requests, register and pre-approve data, provide containers, monitor data, and the like.

The applications 220, 250, 252, and 270 are for instructing the processing devices 214, 244 and 264 to perform various steps of the methods discussed herein, and/or other steps and/or similar steps. In various embodiments, one or more of the applications 220, 250, 252, and 270 are included in the computer readable instructions stored in a memory device of one or more systems or devices other than the systems 152 and 142 and the target device 144. For example, in some embodiments, the application 220 is stored and configured for being accessed by a processing device of one or more third party systems 292 connected to the network 150. In various embodiments, the applications 220, 250, 252, and 270 stored and executed by different systems/devices are different. In some embodiments, the applications 220, 250, 252, and 270 stored and executed by different systems may be similar and may be configured to communicate with one another, and in some embodiments, the applications 220, 250, 252, and 270 may be considered to be working together as a singular application despite being stored and executed on different systems.

In various embodiments, one of the systems discussed above, such as the data loss prevention system 142, is more than one system and the various components of the system are not collocated, and in various embodiments, there are multiple components performing the functions indicated herein as a single device. For example, in one embodiment, multiple processing devices perform the functions of the

12

processing device 244 of the data loss prevention system 142 described herein. In various embodiments, the data loss prevention system 142 includes one or more of the external systems 296 and/or any other system or component used in conjunction with or to perform any of the method steps discussed herein. For example, the data loss prevention system 142 may include a financial institution system, an information technology system, and the like.

In various embodiments, the data loss prevention system 142, the third party system 152, and the target device 144 and/or other systems may perform all or part of a one or more method steps discussed above and/or other method steps in association with the method steps discussed herein. Furthermore, some or all the systems/devices discussed here, in association with other systems or without association with other systems, in association with steps being performed manually or without steps being performed manually, may perform one or more of the steps of method 100, the other methods discussed below, or other methods, processes or steps discussed herein or not discussed herein.

#### Method of Creating Secure Data Containers

Turning now to FIG. 3, a system and method is provided for creating secure data containers, wherein the system provides a virtual container providing selective access to and selective actions regarding files stored in the virtual container. In some embodiments, the system is configured to receive a request to create a container, wherein the container is a file system comprising access parameters that define one or more permitted actions and one or more permitted users for the container. The system then determines duration parameters for the container, wherein the duration parameter comprise a time duration during which the container may be accessed, and determines a fingerprint of the container, the fingerprint being a record of the container for comparison to the container at a later time. In some embodiments, the system then generates the container with the access parameters, duration parameters, and fingerprint; monitors the container for compliance with the access parameters, duration parameters, and fingerprint; and applies a consequence when the container is not in compliance with the access parameters, duration parameters, or fingerprint. The consequence may range from preventing access to the container or file to automatically deleting the container or file.

In block 302, the system receives a request to create a container. In some embodiments, the container is a file system comprising access parameters that define one or more permitted actions and one or more permitted users for the container. In an embodiment, the file system may be a single file stored in memory. In this embodiment, the single file may have access parameters, duration parameters, location parameters, and the like. While this disclosure will refer to file systems with respect to containers or virtual containers, it should be understood that a single file may be considered a container.

In an embodiment, a container is a virtual memory store that is configured to contain one or more files. In some embodiments, the container may be created empty and configured to receive files that are saved or copied to the container. In some embodiments, the container is created around pre-existing files in order to provide additional security for the files. In some embodiments, the container is created to protect the memory store of a removable storage device, such as a USB drive.

In an embodiment, the container is a file system that is configured to receive one or more files. In some embodi-

13

ments, the file system is encrypted and requires encryption technology in order to access or read. In some embodiments, the file system is locked via a password. In some embodiments, the file system is compressed and must be uncompressed prior to access.

In some embodiments, the container includes access parameters instead of or in addition to the encryption, passwords, and/or compression. In an embodiment, access parameters are parameters set up in advance that determine access to the container by permitted users and determine permitted actions that may be taken with respect to the container or to files stored within the container.

In an embodiment, a permitted user is a user that is permitted to access the container and/or at least one file stored in the container. As discussed with respect to FIG. 1, the permitted user may be an individual or a program. The individual may be associated with the financial institution, e.g., an employee, or the individual may be external to the financial institution. The permitted user or users may be stored in a database associated with the container or files stored in the container.

Permitted actions, as discussed with respect to FIG. 1, may be any type of action take on the files or container. For example, access to the container may be a permitted action. In some embodiments, the permitted actions are tied to a specific permitted user. In other embodiments, the permitted actions may be performed by any permitted user. While the examples of permitted actions related to files may be applied to the container as well, it should be understood that additional actions may be performed on containers. For example, a container may be deleted, including all of the contents in the container. In some embodiments, permitted actions for containers relate to coordinated action on the files in the container. For example, a permitted action may permit a plurality of files in the container to be searched or indexed at one time.

In an embodiment, the access parameters are determined when the request is received. For example, a user may specify that a container having specific access parameters, i.e., one or more permitted users and one or more permitted actions, be created. In some embodiments, the access parameters are default parameters for the container or for all containers. In some embodiments, when the container is created around pre-existing files the access parameters may be determined at least in part based on characteristics of the pre-existing files. For example, a container created around video files may control what types of applications may play the video files, or with him the video files may be shared.

In an embodiment, the system receives the request via a computing device processor. For example, the request may be received over a network or via an input device. In some embodiments, a user inputs the request and either defines the parameters or is prompted to enter the parameters by the system. In some embodiments, the request is received to create container without any files stored in the container. In other embodiments, the request is received along with one or more files that will be stored within the container. In some embodiments, the request is received when external storage devices, e.g., USB drives, are input into a computer or server.

In block 304, the system determines a duration parameter for the container. In some embodiments, the duration parameter includes a time duration during which the container may be accessed. In some embodiments, a container is created for a limited time period, such as one week, one month, or the like. In an embodiment, the time duration is the length of time from the creation of the container until the container is

14

no longer accessible to at least one permitted user. In some embodiments, the time duration is the time from creation until the container is no longer accessible to any user. In some embodiments, the time duration starts running from a time different from the creation of the container. For example, the time duration may start running from the time the container is accessed by any user or by a specific permitted user. In further embodiments, the time duration may run from the time a user attempts to access the container but is prevented from doing so for some reason. In an embodiment, a permitted user may reset the time duration if the permitted user provides an input to the container within the time duration. In this manner, if a container is lost and a non-permitted user attempts to access the container, the container will not be accessible after the predetermined time period. In some embodiments, the container is set up to automatically erase the contents of the container at the end of the time duration.

In an embodiment, the duration parameter is received in a manner similar to the access parameters. For example, the duration parameter may be received from a user, may be a default time duration, or may be dependent at least in part on the content of the container. The duration parameter may be applied to the container when the container is created or may be applied at a later date. In some embodiments, different duration parameters apply to different files stored in the container. In an embodiment, the container may have a first duration parameter and the files stored in the container may have duration parameters.

In block 306, the system determines a location parameter for the container. In some embodiments, the location parameter includes a location at which the container may be accessed. Similar to the duration parameters, the location parameter is a predetermined geographic area in which the container or one or more files stored in the container may be accessed by a permitted user. In some embodiments, the container is erased when the system determines that the container is located outside of the location parameters. In some embodiments, one or more files are not accessible outside of a predetermined area. The location parameters permit the user to protect files so that the files are not accessed outside of predefined areas.

In some embodiments, the location of the container or files stored in the container is determined based on a positioning system device associated with the memory store. For example, a GPS unit may be associated with the memory store. The system uses a computing device processor to determine the location. In some embodiments, the system determines the location when the container or device is accessed to determine the current location of the device comprising the container.

In block 308, the system determines a fingerprint of the container. In an embodiment, the fingerprint is a record of the container for comparison to the container at a later time. As discussed herein, the fingerprint may include information on the structure, content, or communication channels of the container and/or the files stores in the container. The system determines the fingerprint using a computing device processor, as discussed with regard to FIG. 1. The fingerprints associated with files may be individually assessed or assessed as a whole with the fingerprint of the container.

In block 310, the system associates the fingerprint with the container. In some embodiments, the fingerprint is stored locally with the container or in a network associated with the container. In some embodiments, the fingerprint is stored inside the container. The system may update the fingerprint

15

of the container anytime that the container or any file in the container is changed based on a permitted action.

In block 312, the system generates the container with the access parameters, duration parameters, location parameters, and/or associated fingerprint. In some embodiments, a computing device processor generates the container with the access parameters, duration parameters, location parameters, and/or associated fingerprint. The computing device processor may install the container on a removable drive, such as a USB drive. In some embodiments, the container is generated and specific files are input into the container upon generation.

In block 314, the system monitors the container for compliance with the access parameters, duration parameters, and/or location parameters. In an embodiment, compliance means that the information associated with the container complies with the parameters defined for the container. For example, the location of the container may be monitored and compared to the location parameters. In some embodiments, the parameters, e.g., access, duration, location, and fingerprint, are continually monitored. In some embodiments, the parameters are only monitored when the container or a file in the container is accessed or when the container or a file in the container is acted upon.

In block 316, the system applies a consequence when the container is not in compliance with the access parameters, the duration parameters, and/or the location parameters. In an embodiment, a consequence is an action taken by the system when the container is not in compliance with at least one of the parameters. The consequences may differ based on the parameter that is not in compliance. For example, an access parameter that is not in compliance—e.g., the container is somehow accessed by a non-permitted user—may cause the file or container to be immediately erased. In another example, a container that is outside of a location parameter boundary may merely not be opened until the container is back within the location parameter. The consequences may be user-defined or default.

The method of creating a secure container disclosed herein provides a method for protecting files or file systems stored in virtual containers. The method may be used to provide additional protection to files, such as access protections, duration protections, and location protections. Other types of protection parameters may also be included in the general disclosure provided herein. For example, time parameters may permit access to containers only during specified times of the day. The method also provides for determining a fingerprint of the container or the files contained therein and comparing the container or files to the fingerprint to ensure that the action is being performed on the correct version. The container provides an additional layer of protection and may be combined with hardware-level protection as well as file-level protection to provide additional security around sensitive data.

#### Method of Using Secure Data Containers

Turning now to FIG. 4, a system and method of using the secure data containers of FIG. 3 is provided. In some embodiments, the use of secure data containers is to permit selective access by individuals that do not have permission to create the secure data containers. For example, a user may be needed to transport and share files in a removable storage device, but the user does not require access to the content of the files. Use of the secure data containers permits an administrator to establish a secure data container that contains the files and selective permissions that allows the

16

secondary user to share the files in the container but not to access the files in the container. Other examples of selective permissions are possible based on the disclosure provided herein.

In block 402, the system determines that a user is accessing a memory store comprising a container. In some embodiments, the container is a file system comprising access parameters that define one or more permitted actions and one or more permitted users for the container. As discussed, a user may be an individual associated with the financial institution or an individual external to the financial institution. In some embodiments, the user is a program or computing device that accesses the container automatically or upon request of a user.

In some embodiments, the memory store is a portion of a drive, a partition, or the like of memory in which the container is stored. In some embodiments, the memory store is identified as a portion of the memory based on a directory structure. In further embodiments, the memory store is memory associated with a removable device, such as a USB drive, a memory chip, or the like.

In block 404, the system determines an identity of the user. The identity of the user may be determined from a user login, a passcode, or the like. In some embodiments, the identity of the user is determined based on a hardware number associated with hardware of the user. In some embodiments, a network address is used to identify the user up to a specific level, e.g., the network address indicates that the user is accessing the container from within the financial institution. In some embodiments, a portion of the identifier is used to provide access. For example, a “.gov” suffix on an email address may identify the user such that the user is accessing the container from a government account.

In block 406, the system determines whether the user has permission to access the container and/or one or more files on the container. In an embodiment, the system compares the identity of the user to the access parameters associated with the container to determine if the user is a permitted user. In some embodiments, the system compares the identity of the user to an allowed list of permitted users available to the system in a database.

In decision block 408, the system determines whether the user has permission. In block 410, the system prevents access to the container when the user does not have permission. Preventing access may mean that the container is hidden from view. In some embodiments, preventing access means that the container is visible but the user cannot review the contents of the container. In still further embodiments, the system erases the container in order to prevent access.

In block 412, the system displays the container and/or the one or more files to the user when the user is allowed to access the container. The user may be able to open the container and view the files listed in the container. In an embodiment, the user is able to view the containers is a directory structure or folder format. In some embodiments, metadata relating to the files are also available, such as creation date, size, creator, last access date, or the like. In some embodiments, the user may be able to access the container but not able to view the contents of the files in the container.

In block 414, the system determines that the user is accessing one or more of the files. As discussed herein, accessing may depend on the type of file. For example, a database may be accessed when a communication channel is opened to the database. In another example, a document is accessed when the document is opened, copied, moved, or the like. The system determines that the user is accessing the

17

one or more files based upon a command initiated by the user related to the file, e.g., open, copy, and the like.

In block **416**, the system compares the file to a fingerprint of the file. The fingerprint of the file is created when the file is most recently changed by a permitted action. The fingerprint is stored in association with the file, such as in the container, locally to the memory store, or on a network accessible to the container. As discussed, the system compares the file via a computing device processor. In some embodiments, a checksum is created to determine whether the file and the fingerprint are a match based on the structure, the content, and/or the communication channels associated with the file. In an embodiment, the comparison is carried out by a computing device processor. The comparison may evaluate any one of or all of the structure, the content, and the communication channels of the file. The structure of the file is the data structure comprising the file. For example, the number of columns or rows in a spreadsheet may be part of the structure of the spreadsheet. The content of the file is the data input into the file. The information in cells of the spreadsheet or the words and figures in a document are the content of the file. The communication channels are the connections between the file and external elements. For example, if a spreadsheet is automatically updated via an input interface, the connection to the input interface may be a part of the comparison. In some embodiments, a checksum calculation is used to determine whether the fingerprint is identical to the file or is similar to the file within a predetermined level of confidence, e.g., 99% or 95%. In further embodiments, dynamic data associated with the file is not included in the comparison. In other embodiments, however, the file is a static file.

In decision block **418**, the system determines whether the file matches the fingerprint. A match may mean an identical match in all areas that the system is evaluating, e.g., structure, content, communication channels. In some embodiments, a text comparison is performed to identify changes such as updates, new versions, edits, or deletions to the content of the file. In some embodiments, specific portions of the files are excluded from the analysis. For example, portions or metadata related to files may be excluded if these portions typically change without changing content. For example, current date or time may be recorded in the metadata when a file is accessed but this data does not indicate that the file changed from the time the fingerprint was created. In some embodiments, the match is within a specific level of similarity, e.g., 100% similarity, 99% similarity, 95% similarity, or the like. Algorithms for comparing files and determining levels of similarity or difference may be used.

In block **420**, the system prevents access to the file when the file does not match the fingerprint. As with the container in general, the system may not allow the user to perform an action on the file if the fingerprint does not match. For example, the user may not send the file to an external party if the fingerprint does not match. This prevents the user from sending a different version of the file to an external party as opposed to the version that was pre-approved for dissemination.

In block **422**, the system permits access to the file when the file matches the fingerprint. If the user has access and the fingerprint matches the file, the user may be able to access the file. As discussed in FIG. 1, when a user accesses a file the user may be able to perform all actions on the file or the system may have a list of permitted actions that the user may perform on the file. In one use case, a user may be able to access a USB drive and copy files from the USB drive onto

18

a remote drive, e.g., an ATM, but the user does not have permission to read the content on the drive. In some embodiments, the container may be remote wiped by an authorized user. For example, if the container is accessible to a network the user may remotely erase the files in the container if the user is a permitted user and remote erase is a permitted action for the user.

The method of using secure containers is related to the method of creating secure containers. Rather than providing container parameters and establishing the container, the method of using describes a system and method whereby the container actively protects files from unauthorized access and unauthorized actions, and compares the file to the fingerprint to ensure that the proper version is being acted upon. The container may also implement parameters related to access, such as duration, location, encryption, compression, and the like. The method of using describes how the secure container may be used to provide additional security to sensitive data.

#### Secure Access to Programming Data

The process embodiments discussed hereinabove largely describe data transfers for end users such as employees, associates, or other users who may need to transfer files or other data. In the embodiments described below with regard to FIG. 5, I/O and/or OS codes associated with certain tasks are transferred between devices or systems.

FIG. 5 illustrates a flowchart providing an overview of a process **500** for securing access to programming data. The process **500** can include one or more steps of the processes **100**, **300**, and **400** discussed above. One or more devices, such as the one or more computing devices and/or one or more other computing devices and/or servers of FIG. 2, can be configured to perform one or more steps of the process **500** described below. In some embodiments, the one or more devices performing the steps are associated with a financial institution. In other embodiments, the one or more devices performing the steps are associated with a business, partner, third party, developer, employee, and/or user.

As illustrated at block **502**, task protocols and registration requests are received and/or retrieved. Task protocols include parameters associated with performing tasks such as debugging, troubleshooting, small code variance, program updates, system checks, and so forth. The task protocols may be retrieved from a third party system. For example, vendors may allow the system of process **500** to retrieve the task protocols from system libraries, or the vendors may send the task protocols to the system. By gaining access to the task protocols before a task is performed, the system can anticipate what codes will be needed to perform the task and can make an informed decision as to whether unnecessary code should be blocked as discussed in more details below.

The registration requests can be received from associates, developers, managers, and other parties. The registration requests enable certain data to be pre-approved for dissemination or input. In some embodiments, associates send the registration request to a manager who reviews the request and approves all or a portion of the data in the request for pre-approval and registration. In other embodiments, the registration process is completed automatically. The system of process **500** may, for example, approve or deny registration based on established protocols that prevent confidential and proprietary data from being exposed.

The registration request includes code or other data sought to be pre-approved, and can further include additional information such as reasons for seeking registration,

certifications that the data does not contain confidential information, user access limits, pre-approval time limits, and the like. For example, the registration request may include certain source code, the identity of the users to be granted permission to access the certain source code, types of data modification (copy, read only, write, and so forth) allowed for each identified user, and an allotted amount of time for performing the task. In one exemplary case, some users may be allowed to copy the data while other users may only be allowed to read the data.

As illustrated at block **504**, an allowed list is determined based on the task protocols and/or the registration requests, where the list includes code necessary to execute a specific task, registered data, and so forth. The necessary task code includes code for performing specific tasks such as troubleshooting, debugging, system or program updates, patch installations, small code variance, and so forth. The necessary task code is identified from the task protocols received or retrieved from internal sources or third parties (e.g., vendors servicing a device or systems and programs installed on the device). The registered data includes the pre-approved data discussed above. In cases where a specific task (e.g., debugging) is to be performed, the system matches the specific task from registered data stored in a registration database. In this way, the system can streamline the process by limiting the registered data to only the data pertinent to the task. In other embodiments, the system may include registered data associated with a user, the device, or programming associated with the device in the allowed list.

As illustrated at block **506**, a user is allowed to establish a connection to a device in order to execute the specific task. The device includes one or more computing devices such as laptops, personal computers, notepads, gaming devices, smart phones, cell phones, other mobile devices, and the like. In the embodiment of FIG. 5, the user includes developers, technical support staff, vendors associated with the device, program specific programmers, and other third parties. In additional embodiments, the user can include any party associated with the device such as the owner of the device, an internal associate, an employee, and the like.

In some embodiments, the system includes granular permissions based on the user. For example, the needs of a developer and tester may differ. Once the user establishes a connection, in some embodiments the identity of the user is determined and the granular permissions for access to the data are determined based on the identity of the user. For example, a developer may have greater write access to limited portions of the data, while a tester may have only read access to a greater portion of the data. This access control permits different access levels for different specific and/or categories of users. In this embodiment, the granular permissions based on the user also assist the system in managing access as users change positions. For example, if a user who was once a developer switches to be a tester then the access the user has will also change based on the category of the user. This also allows the system to quickly and easily revoke access to data by changing the granular permissions associated with specific and/or categories of users.

In further embodiments, a removable device is connected to the device. For example, one or more removable devices such as a USB (universal serial bus) flash drive, external hard drive, CD, and other removable media can be connected to the device. The removable device can include a virtual container comprising a removable media.

In other embodiments, a third party system is wirelessly connected to the device. For example, a vendor system may access the device via a wireless network to conduct low level debugging.

As illustrated at block **508**, any data on the device that is being accessed by the user including data being transferred to and/or from the device is identified and monitored. For example, the system of process **500** may receive connection information whenever an external removable media is mounted to the device. The system identifies the external removable media and tracks the data being accessed by the external removable media. In other cases, the system may detect wireless connections and identify the data being accessed by the third party system.

Once the connection is established, the user may only have read-only capabilities, or the user may be able to copy, add, delete, or otherwise modify data on the device depending on permissions granted to the user. Further, the user may only have access to certain portions of the data stored or otherwise associated with the device. The system of process **500** monitors all the data that is accessed, imported, or exported by the user including specific code, object level calls, and the like.

As illustrated at determination block **510**, the system of process **500** determines if the identified accessed data is included in the allowed list. The system, in some embodiments, compares the necessary task codes, registered data, or other pre-approved data to the identified accessed data. Based on the comparison, the system can determine if a portion of the accessed data does not match the data of the allowed list. For example, a developer may be allowed to write code for debugging because it is in the allowed list or otherwise necessary for performing the specific task. However, details put in parenthesis such as comments on how something operates would be disallowed.

In a further embodiment, the system may include high level permissions for development, debugging, and/or operating system upgrades. For example, the system may determine that an input to the protected memory may be an operating system upgrade. The system determines this based on metadata associated with the input, based on diagnostic code included with the input, or the like. In this embodiment, the system does not conduct a lengthy review or change process but instead determines that the upgrade is on an allowed list and then permits the upgrade to occur. In some embodiments, the input includes an identifier that allows the input to pass through the protections without needing the system to be re-engineered. For example, the identifier may act as a flag or a switch that turns the protection off when the identifier is included with the input or output. In this manner, a user could override the protections by including a pre-determined identifier with the data that is passing through the system.

As illustrated at decision block **512**, if it is determined that the identified accessed data is not allowable, the system of process **500** determines if the accessed data is proprietary, confidential, or otherwise impermissible. In cases where the system included only registered data associated with the specific task, user, or device in the allowed list, the system may conduct a secondary search of pre-approved data stored in the registration database to determine if the accessed data matches any of the pre-approved data. In other cases, the system conducts content searching. For example, the system may conduct content searching of the accessed data to identify government identifiers, passwords, protected data, personal information, and other data by using key words, search strings, and Boolean operators.

## 21

In some embodiments, all or pre-determined portions of the accessed data that does not match the data in the allowed list is subjected to the secondary inquiry of block 512. For example, if the specific task is time sensitive or tagged as critical, the accessed data may undergo the secondary inquiry to avoid unnecessary delays that would otherwise occur if the process 500 was terminated, or to aid in allowing the user to complete the task. In other examples, the method of access or the type of accessed data may determine whether or not the non-matching accessed data is subjected to the secondary inquiry. For example, if the data is only being read and not copied or modified, the system may allow the non-matching accessed data to continue to the next steps of the process 500. In other examples, certain types of data that are highly unlikely to contain confidential or proprietary information may be subjected to the second inquiry.

If the system determines that the accessed data is not impermissible, the process 500 continues to block 516. If the system determines that the accessed data is impermissible, the process 500 continues to block 514.

As illustrated at block 514, action is taken to prevent or stop transfer of disallowed data. Action can be taken automatically in response to determining that the accessed data does not match the data of the allowed list, or the system can further assess the accessed data as discussed above with regard to block 512.

Any number of actions can be taken to prevent or stop the transfer of the disallowed data. In some embodiments, the connection is terminated. For example, the system of process 500 may unmount the removable media from the device or sever the wireless connection. In other embodiments, the system blocks impermissible data from being accessed or modified. For example, the system may completely block off the impermissible or disallowed data from being read, copied, and modified, or the system may allow the disallowed data to be read but not copied or modified.

As illustrated at block 516, data access, data transfer, or data modification is allowed to continue until an issue arises, the task is completed, or the connection is terminated if it is determined that all of the accessed data matches the data of the allowed list or if it determined that the non-matching accessed data is permissible. Loss of power supply, command errors, or complete loss of connection may terminate the process such that the process 500 must be started over from the beginning. For example, the device may automatically shut down, data transfer may stop, or removable media may be accidentally or purposefully unmounted from the device.

In further embodiments, one or more reports are generated. The reports can include a log of the data that was transferred between the device and an external media or system, any data modification on the device, time and date the task is completed, issues arising during performance of the task, recommendations for pre-approvals for certain data, and the like. The reports can be used to make adjustments and optimize the process. For example, if certain tasks were prevented from being completed over 50% of the time because the system determined that certain types of data were not allowable, the one or more reports may recommend that the task protocols be updated or that the certain types of data be registered to avoid delays in the future.

The flowcharts and block diagrams in the figures illustrate the architecture, functionality, and operation of possible implementations of systems, methods and computer program products according to various embodiments of the present disclosure. In this regard, each block in the flowchart or block diagrams may represent a module, segment, or

## 22

portion of code, which comprises one or more executable instructions for implementing the specified logical function(s). It should also be noted that, in some alternative implementations, the functions noted in the block may occur out of the order noted in the figures. For example, two blocks shown in succession may, in fact, be executed substantially concurrently, or the blocks may sometimes be executed in the reverse order, depending upon the functionality involved. It will also be noted that each block of the block diagrams and/or flowchart illustration, and combinations of blocks in the block diagrams and/or flowchart illustration, can be implemented by special purpose hardware-based systems which perform the specified functions or acts, or combinations of special purpose hardware and computer instructions.

The terminology used herein is for the purpose of describing particular embodiments only and is not intended to be limiting of embodiments of the disclosure. As used herein, the singular forms "a," "an," and "the" are intended to include the plural forms as well, unless the context clearly indicates otherwise. It will be further understood that the terms "comprises" and/or "comprising," when used in this specification, specify the presence of stated features, integers, steps, operations, elements, and/or components, but do not preclude the presence or addition of one or more other features, integers, steps, operations, elements, components, and/or teams thereof.

The corresponding structures, materials, acts, and equivalents of all means or step plus function elements in the claims below are intended to include any structure, material, or act for performing the function in combination with other claimed elements as specifically claimed. The description of the present disclosure has been presented for purposes of illustration and description, but is not intended to be exhaustive or limited to embodiments of the disclosure in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in the art without departing from the scope and spirit of embodiments of the disclosure. The embodiment was chosen and described in order to best explain the principles of embodiments of the disclosure and the practical application, and to enable others of ordinary skill in the art to understand embodiments of the disclosure for various embodiments with various modifications as are suited to the particular use contemplated. Although specific embodiments have been illustrated and described herein, those of ordinary skill in the art appreciate that any arrangement which is calculated to achieve the same purpose may be substituted for the specific embodiments shown and that embodiments of the disclosure have other applications in other environments. This application is intended to cover any adaptations or variations of the present disclosure. The following claims are in no way intended to limit the scope of embodiments of the disclosure to the specific embodiments described herein.

What is claimed is:

1. A system for providing secure data access, wherein the system provides selective access to and selective actions regarding files, the system comprising:

- a computer apparatus including a processor and a memory; and
- a software module stored in the memory, comprising executable instructions that when executed by the processor cause the processor to:
  - determine that a file has been created or received;
  - determine a fingerprint of the file, wherein the fingerprint is a record of a structure, a content, and

23

communication channels of the file at a first point in time for comparison to the file at a later point in time; scan the file to identify keywords and data types; automatically assign at least one permitted use related to the file based on the identified keywords and data types, wherein the permitted uses comprises a permitted user and a permitted action; store the fingerprint and the permitted use in association with the file; determine that the file is being accessed by a user; determine whether the user is a permitted user of the file based on an identity of the user; transmit an alert to a creator of the file when the user is not a permitted user, wherein the alert notifies the creator of the file that the user is not a permitted user; compare the file at the later point in time to the fingerprint of the file when the user is a permitted user, wherein the comparison of the file to the associated fingerprint of the file excludes dynamic metadata, and wherein dynamic metadata comprises descriptive data of the file that regularly changes but does not change content of the file; determine a level of confidence of matching for the comparison of the file at the later point in time and the fingerprint; determine that the file at the later point in time is in compliance with the fingerprint by determining that the level of confidence is above a predetermined threshold level of confidence; determine an action being taken by the user, in response to determining that the file at the later point in time is in compliance with the fingerprint; and permit the action to occur when the action is a permitted action of the file.

2. The system of claim 1, wherein the permitted action is selected from the group consisting of writing to the file, reading the file, copying the file, deleting the file, and sharing the file.

3. The system of claim 1, wherein the software module further comprises executable instructions that when executed by the processor cause the processor to: update the fingerprint when the action is a permitted action.

4. The system of claim 1, wherein the identity of the user is determined based on a comparison of a database to information associated with the user selected from the group consisting of a username, a password, a network address, and a portion of an email address.

5. The system of claim 1, wherein the software module further comprises executable instructions that when executed by the processor cause the processor to: track the actions performed by the permitted user.

6. A computer program product for providing secure data access, the computer program product comprising: a non-transitory computer readable storage medium having computer readable program code embodied therein; the computer readable program code comprising: computer readable program code configured to determine that a file has been created or received; computer readable program code configured to determine a fingerprint of the file, wherein the fingerprint is a record of a structure, a content, and communication channels of the file at a first point in time for comparison to the file at a later point in time; computer readable program code configured to scan the file to identify keywords and data types;

24

computer readable program code configured to automatically assign at least one permitted use related to the file based on the identified keywords and data types, wherein the permitted uses comprises a permitted user and a permitted action;

computer readable program code configured to store the fingerprint and the permitted use in association with the file;

computer readable program code configured to determine that the file is being accessed by a user;

computer readable program code configured to determine whether the user is a permitted user of the file based on an identity of the user;

computer readable program code configured to transmit an alert to a creator of the file when the user is not a permitted user, wherein the alert notifies the creator of the file that the user is not a permitted user;

computer readable program code configured to compare the file at the later point in time to the fingerprint of the file when the user is a permitted user, wherein the comparison of the file to the associated fingerprint of the file excludes dynamic metadata, and wherein dynamic metadata comprises descriptive data of the file that regularly changes but does not change content of the file;

computer readable program code configured to determine a level of confidence of matching for the comparison of the file at the later point in time and the fingerprint;

computer readable program code configured to determine that the file at the later point in time is in compliance with the fingerprint by determining that the threshold level of confidence is above a predetermined level of confidence;

computer readable program code configured to determine an action being taken by the user, in response to determining that the file at the later point in time is in compliance with the fingerprint; and

computer readable program code configured to permit the action to occur when the action is a permitted action of the file.

7. The computer program product of claim 6, wherein the permitted action is selected from the group consisting of writing to the file, reading the file, copying the file, deleting the file, and sharing the file.

8. The computer program product of claim 6, wherein the computer readable program code further comprises: computer readable program code configured to update the fingerprint when the action is a permitted action.

9. The computer program product of claim 6, wherein the identity of the user is determined based on a comparison of a database to information associated with the user selected from the group consisting of a username, a password, a network address, and a portion of an email address.

10. The computer program product of claim 6, wherein the computer readable program code further comprises: computer readable program code configured to track the actions performed by the permitted user.

11. A computer-implemented method for providing secure data access, the method comprising: determining, via a computing device processor, that a file has been created or received; determining, via a computing device processor, a fingerprint of the file, wherein the fingerprint is a record of a structure, a content, and communication channels of the file at a first point in time for comparison to the file at a later point in time;

## 25

scanning, via a computing device processor, the file to identify keywords and data types;  
 automatically assign, via a computing device processor, at least one permitted use related to the file based on the identified keywords and data types, wherein the permitted uses comprises a permitted user and a permitted action;  
 storing, in a database, the fingerprint and the permitted use in association with the file;  
 determining, via a computing device processor, that the file is being accessed by a user;  
 determining, via a computing device processor, whether the user is a permitted user of the file based on an identity of the user;  
 transmitting, via a computing device processor, an alert to a creator of the file when the user is not a permitted user, wherein the alert notifies the creator of the file that the user is not a permitted user;  
 comparing, via a computing device processor, the file at the later point in time to the fingerprint of the file when the user is a permitted user, wherein the comparison of the file to the associated fingerprint of the file excludes

## 26

dynamic metadata, and wherein dynamic metadata comprises descriptive data of the file that regularly changes but does not change content of the file;  
 determining, via a computing device processor, a level of confidence of matching for the comparison of the file at the later point in time and the fingerprint;  
 determining, via a computing device processor, that the file at the later point in time is in compliance with the fingerprint by determining that the level of confidence is above a predetermined threshold level of confidence;  
 determining, via a computing device processor, an action being taken by the user, in response to determining that the file at the later point in time is in compliance with the fingerprint; and  
 permitting the action to occur when the action is a permitted action of the file.

**12.** The computer-implemented method of claim 11, wherein the permitted action is selected from the group consisting of writing to the file, reading the file, copying the file, deleting the file, and sharing the file.
